Dr. G. PONKUMAR
ASSISTANT PROFESSOR

ACKNOWLEDGEMENT

Our sincere thanks to our Honourable Founder and Chairman**, Dr. JEPPIAAR, M.A., B.L., Ph.D.,** for his sincere endeavor in educating us in his premier institution.

We would like to express our deep gratitude to our beloved Secretary and Correspondent, **Dr. P. CHINNADURAI, M.A., M.Phil., Ph.D** for his enthusiastic motivation which inspired us a lot in completing this project and our sincere thanks to our Directors **Mrs. C. VIJAYA RAJESWARI, Dr. C. SAKTHI KUMAR, M.E., Ph.D** and **Dr. SARANYASREE SAKTHIKUMAR, B.E, M.B.A, Ph.D** for providing us with the necessary facilities for the completion of this project.

We would like to express thanks to our Principal, **Dr. K. MANI M.E., Ph.D.,** for having extended his guidance and cooperation.

We would also like to thank our Head of the Department, **Dr. S. SELVI, M.E., Ph.D.,** Professor and Head, Department of Electrical and Electronics Engineering for her encouragement.

Personally, we thank our Guide **Dr. G. PONKUMAR** in the Department of Electrical and Electronics Engineering for the persistent motivation and support for this project, who at all times was the mentor of germination of the project from a small idea to a complete working system.

We express our sincere thanks to the project coordinators in the Department of Electrical and Electronics Engineering for their valuable suggestions from time to time at every stage of our project.

Finally, we would like to take this opportunity to thank our family members, faculty and non-teaching staff members of our department, friends, and well-wishers who have helped us for the successful completion of this project.

ABSTRACT

Fire incidents represent one of the most devastating hazards in modern industrial, residential, and public environments. Traditional fire detection systems are primarily designed to sense smoke or heat beyond certain threshold values, offering a simple binary alarm without any intelligence about the nature of the fire or its origin. This lack of specificity often results in delayed emergency response, improper use of fire-fighting agents, and increased casualties and property damage.

This project proposes and implements a Smart Fire Source Identification System using Multi-Gas Sensor Fusion. Instead of merely detecting fire or smoke, the proposed system intelligently identifies the burning material by analyzing the unique gas signature produced during combustion. Different materials such as wood, plastic, paper, rubber, and electrical equipment produce distinctly different combinations of combustion gases including Carbon Monoxide (CO), Liquefied Petroleum Gas (LPG), Volatile Organic Compounds (VOCs), and particulate smoke. By deploying three gas sensors — MQ-2 (smoke and LPG), MQ-7 (Carbon Monoxide), and MQ-135 (air pollutants and VOCs) — in a sensor fusion architecture, the system captures multi-dimensional gas concentration data in real time.

A microcontroller-based processing unit, implemented on an ESP32 module, reads the analog outputs from all three sensors simultaneously and applies a rule-based classification algorithm to identify the likely burning material. The system provides alerts through an integrated buzzer and LED indicators, and can optionally transmit data wirelessly via the built-in Wi-Fi capability of the ESP32 module.

The experimental results demonstrate that the proposed system successfully classifies five categories of fire sources — wood/paper fires, plastic fires, rubber fires, electrical fires, and LPG/gas leaks — with high accuracy under controlled laboratory conditions. The system is compact, low-cost, scalable, and suitable for deployment in buildings, warehouses, factories, hospitals, and transportation facilities. The proposed architecture provides a foundation for future integration with artificial intelligence-based classification models, IoT cloud monitoring platforms, and autonomous fire-suppression systems.

CHAPTER 1
INTRODUCTION

1.1 INTRODUCTION

Fire is one of the most destructive natural and man-made hazards faced by modern civilization. Whether in industrial facilities, residential buildings, hospitals, warehouses, or transportation systems, fire incidents cause enormous loss of life and property every year. According to global fire statistics, millions of fire-related incidents occur annually, with a significant proportion resulting from electrical faults, gas leaks, and uncontrolled combustion of various materials. Rapid and accurate detection of fire — and crucially, identification of its source — is therefore a matter of profound importance.

Conventional fire detection systems rely primarily on smoke detectors, heat sensors, or flame sensors that trigger a binary alarm when their threshold is exceeded. While these systems are effective at detecting fire presence, they provide no information about the nature or origin of the fire. This limitation significantly hampers emergency response, as fire-fighters and safety personnel must manually investigate the situation before selecting appropriate suppression strategies.

The advent of semiconductor gas sensing technology has opened new possibilities for intelligent fire detection. Different combustion processes produce unique chemical signatures in the surrounding air. Wood fires predominantly release carbon monoxide and particulate smoke. Plastic fires are characterized by high concentrations of volatile organic compounds. Electrical fires produce a distinctive burnt odor with minimal smoke. By measuring and analyzing these gas profiles, it becomes possible to identify the likely source of a fire before it spreads.

This project proposes a Smart Fire Source Identification System that leverages multi-gas sensor fusion to achieve intelligent fire detection and source classification. The system integrates three commercially available gas sensors with a microcontroller to provide real-time analysis of combustion gases, enabling both detection and classification of fire sources.

1.2 GROWTH OF FIRE HAZARDS AND DETECTION TECHNOLOGIES

Urbanization, industrialization, and the proliferation of synthetic materials have collectively increased fire risks in the modern world. Synthetic polymers, which are used extensively in construction, furniture, electronics, and packaging, produce highly toxic combustion products when burned. LPG and natural gas usage in residential and industrial settings introduces the risk of explosive gas leaks and fires. As environments become more complex and materials more diverse, the need for sophisticated fire detection systems has grown substantially.

Fire detection technology has evolved from simple bimetallic heat strips used in early sprinkler systems to photoelectric smoke detectors, ionization detectors, and multi-criteria detectors. However, even modern multi-criteria detectors that combine smoke and heat sensing do not provide source identification capabilities. Research in the field of electronic nose (e-nose) technology and gas sensor arrays has demonstrated the potential for chemical fingerprinting of combustion events, providing the conceptual foundation for this project.

The integration of low-cost, miniaturized gas sensors with powerful microcontrollers capable of onboard data processing has made intelligent fire source identification a viable proposition. The proposed system builds upon these technological developments to provide a practical, deployable solution.

1.3 COMBUSTION GAS ANALYSIS

When a material undergoes combustion, it reacts with atmospheric oxygen to release heat, light, and various chemical products. The specific gases produced depend on the elemental composition of the burning material, the availability of oxygen, and the combustion temperature. Understanding these combustion chemistry relationships is fundamental to the design of the proposed fire source identification system.

Fig 1.3.1 Combustion Gas Analysis Diagram

Carbon-based materials such as wood, paper, and cotton produce primarily carbon dioxide (CO2) and carbon monoxide (CO) under incomplete combustion, along with water vapor. Synthetic polymers such as polyvinyl chloride (PVC), polyethylene (PE), and polystyrene (PS) produce complex mixtures of VOCs, benzene, formaldehyde, and halogen compounds. Rubber combustion releases sulfur dioxide and particulates. Electrical insulation materials produce a characteristic acrid smell from decomposing polyimides and epoxies.

By using sensor arrays sensitive to CO, LPG, and general air pollutants, it is possible to construct a multi-dimensional gas concentration vector for each combustion event. Pattern matching of this vector against known gas signatures enables automated classification of the fire source.

1.4 IMPORTANCE OF SENSOR FUSION

Sensor fusion refers to the technique of combining data from multiple sensors to achieve information that is more accurate, complete, or reliable than what any single sensor could provide independently. In the context of fire detection, a single gas sensor can detect the presence of a

particular gas but cannot reliably distinguish between different fire sources that may produce the same gas at different concentrations.

The MQ-2 sensor responds to smoke, LPG, butane, hydrogen, and methane. The MQ-7 sensor is specifically optimized for carbon monoxide detection. The MQ-135 sensor responds to ammonia, benzene, alcohol, and general air quality degradation. Together, these three sensors create a three-dimensional gas concentration space in which different fire sources occupy distinct and identifiable regions.

Sensor fusion also improves robustness against false alarms. Environmental factors such as cooking smoke, exhaust fumes, or chemical vapors may trigger a single gas sensor, but the combined signature from multiple sensors is far less likely to mimic an actual fire source pattern.

1.5 CHALLENGES IN CONVENTIONAL FIRE DETECTION

Conventional fire detection systems face several significant challenges that limit their effectiveness in modern environments. Firstly, single-criterion detectors based only on smoke or heat are prone to false alarms triggered by cooking, steam, dust, or aerosol sprays. These false alarms cause disruption, erode trust in detection systems, and may lead occupants to ignore genuine alarms.

Secondly, conventional systems provide no information about the nature or location of the fire source. Emergency responders must conduct hazardous manual investigations to determine whether to use water, CO2, foam, or powder extinguishers. Incorrect suppression agent selection can worsen the situation, for example, applying water to an electrical fire creates electrocution hazards.

Thirdly, existing systems typically provide no data logging or network connectivity, making post-incident analysis difficult. Modern safety regulations increasingly require data recording and remote monitoring capabilities that conventional detectors cannot provide.

The proposed system directly addresses all these challenges by providing intelligent source identification, multi-sensor redundancy for false alarm reduction, and optional wireless connectivity for remote monitoring.

1.6 NEED FOR THE PROPOSED SYSTEM

The limitations of existing fire detection technologies create a clear need for a more intelligent and informative system. Industrial facilities processing multiple types of materials need to know not just that a fire has started, but what is burning, in order to activate the correct suppression system and evacuate only the affected zones. Hospitals need sensitive detection that can distinguish between authentic fire events and the gases produced by medical sterilization processes.

The proposed Smart Fire Source Identification System fulfills these needs by providing fire detection, source identification, and alert generation in a compact, affordable, and deployable package. The system is designed to complement existing fire safety infrastructure rather than replace it, providing an additional layer of intelligent analysis that enhances overall safety.

Furthermore, the ESP32-based implementation provides Wi-Fi connectivity that enables integration with building management systems, cloud-based monitoring platforms, and smartphone notification applications, expanding the utility of the system beyond what conventional detectors can offer.

1.7 OBJECTIVES

The primary objective of this project is to design and implement a smart fire detection and source identification system that surpasses the capabilities of conventional fire alarms by providing multi-dimensional gas analysis and material classification.

The specific objectives of the project are as follows:

- To design a multi-gas sensor fusion architecture for intelligent fire detection
- To implement a classification algorithm capable of identifying burning materials
- To develop an embedded system using ESP32 microcontroller for real-time processing
- To provide immediate alerts through buzzer and LED indicators
- To enable wireless notification via ESP32 Wi-Fi for remote monitoring
- To achieve accurate classification of wood, plastic, paper, rubber, and electrical fires
- To demonstrate the system under controlled experimental conditions
- To create a scalable and cost-effective solution for real-world deployment

CHAPTER 2

SYSTEM ANALYSIS

2.1 INTRODUCTION

System analysis is a critical phase in engineering project development that involves a comprehensive examination of existing solutions, their shortcomings, and the requirements for an improved design. In the context of fire detection, system analysis requires an understanding of current sensor technologies, classification approaches, microcontroller platforms, and communication protocols applicable to safety systems.

This chapter presents a detailed analysis of the problem domain, examines existing fire detection systems and their limitations, and establishes the technical rationale for the proposed multi-gas sensor fusion approach. The analysis draws upon published research, industry standards, and practical observations to build a comprehensive understanding of the challenges that the proposed system aims to address.

The analysis reveals that while the individual technologies required for intelligent fire source identification have been independently demonstrated in research settings, no affordable, integrated hardware solution has been brought to the market that combines gas sensor fusion with embedded classification intelligence. This gap represents the primary motivation and opportunity for this project.

2.2 PROBLEM STATEMENT

The rapid growth of industrialization, urbanization, and the widespread use of diverse synthetic materials have dramatically increased the complexity of fire hazards in modern environments. Existing fire detection systems, which predominantly rely on smoke concentration or fixed heat thresholds, are fundamentally inadequate for the demands of contemporary safety engineering for several reasons.

First, current systems cannot distinguish between different types of fires. A smoke alarm triggered by a smoldering electrical cable provides the same alert as one triggered by a wood fire, despite

the fact that these two incidents require completely different response strategies. This lack of specificity leads to suboptimal emergency response and potentially dangerous decisions.

Second, false alarm rates in conventional smoke detectors remain unacceptably high. Steam from bathrooms, cooking smoke, cigarettes, and dust all regularly trigger nuisance alarms, causing alarm fatigue and reducing the credibility of detection systems. A more intelligent system that analyzes gas composition rather than just smoke density would be far more selective.

Third, there is no mechanism in conventional systems for data logging or wireless communication, making it impossible to monitor trends, conduct post-incident analysis, or integrate fire detection with smart building management systems.

The proposed system addresses these problems by implementing a multi-gas sensor fusion approach with embedded classification intelligence, providing a fundamentally more informative and reliable fire detection capability.

2.3 EXISTING SYSTEM

The current generation of fire detection systems encompasses several distinct technologies, each with specific strengths and weaknesses. Ionization smoke detectors use a small radioactive source to ionize air molecules between two charged plates. When smoke particles enter the chamber, they reduce the ionization current, triggering the alarm. These detectors are highly sensitive to fast-flaming fires but less responsive to slow, smoldering fires.

Photoelectric smoke detectors use a light source and photodetector in a light-scattering geometry. Smoke particles entering the detection chamber scatter light onto the photodetector, triggering the alarm. These detectors are more sensitive to slow, smoldering fires and produce fewer false alarms from cooking smoke than ionization detectors.

Fixed-temperature heat detectors trigger when the ambient temperature exceeds a predefined threshold, typically 57°C or higher. Rate-of-rise heat detectors trigger when the temperature increases at more than a specified rate per minute. Heat detectors are immune to smoke nuisance alarms but activate much later in a fire's development, by which time significant damage may already have occurred.

Flame detectors sense the infrared or ultraviolet radiation characteristic of open flames. They are used in environments where rapid flame detection is critical, such as aircraft hangars or oil refineries, but they cannot detect smoldering fires that produce no visible flame.

Detector Type	Smoke Detection	Heat Detection
Ionization	HIGH	LOW
Photoelectric	HIGH	LOW
Heat Detector	NONE	HIGH
Flame Detector	LOW	MEDIUM
Proposed System	HIGH	MEDIUM

Fig 2.3.1 Existing Fire Detection System Comparison

2.4 DRAWBACKS OF EXISTING SYSTEM

The existing fire detection technologies share several critical drawbacks that motivate the development of the proposed intelligent system. These drawbacks are categorized as follows:

- Single-criteria detection: Existing systems detect only one physical parameter (smoke density, temperature, or radiation), providing insufficient information for source identification.
- No material classification: Without knowledge of what is burning, emergency responders cannot select appropriate suppression strategies, potentially worsening the incident.
- High false alarm rates: Ionization and photoelectric detectors are prone to nuisance alarms from cooking, steam, dust, and other non-fire sources.
- No data connectivity: Conventional detectors provide only local audible alarms with no data logging, wireless notification, or integration with building management systems.
- No adaptive thresholds: Fixed threshold detectors cannot adapt to gradual changes in baseline environmental conditions, leading to drift-related performance degradation.
- High cost of intelligent systems: Commercial multi-criteria detectors with even basic classification capability are prohibitively expensive for widespread deployment.
- Delayed response in smoldering fires: Heat-based detectors respond too slowly to smoldering fires, which account for a significant proportion of fire fatalities.

- Lack of scalability: Existing systems are not designed for scalable deployment with centralized monitoring across large facilities.

2.5 NEED FOR THE PROPOSED SYSTEM

The analysis of existing systems clearly establishes the need for a more intelligent, multi-dimensional, and connected fire detection solution. The proposed Smart Fire Source Identification System directly addresses each of the identified drawbacks through its multi-gas sensor fusion architecture, embedded classification algorithm, and wireless connectivity.

By analyzing the concentrations of carbon monoxide, LPG, smoke, and VOCs simultaneously, the proposed system can distinguish between fire sources with a specificity that is fundamentally impossible for single-criterion detectors. The rule-based classification algorithm provides immediate source identification without requiring expensive computational resources.

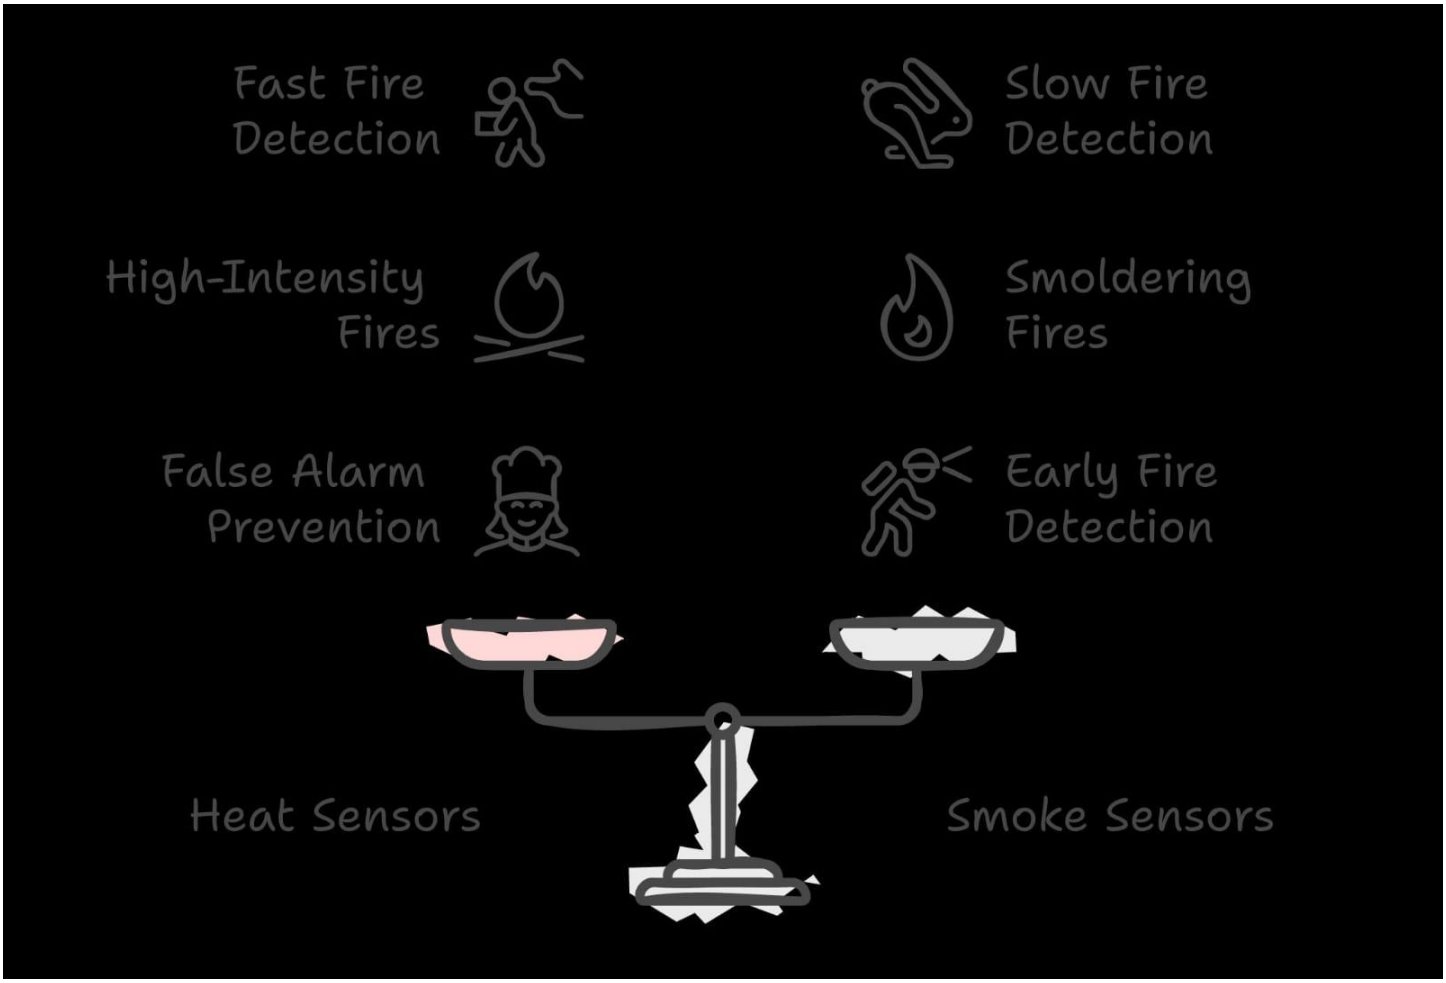

Fig 2.5.1 Need for Proposed System

CHAPTER 3

PROPOSED SYSTEM

3.1 INTRODUCTION

The proposed Smart Fire Source Identification System is built around the principle of multi-gas sensor fusion combined with embedded classification intelligence. Rather than detecting a single gas or physical parameter, the system simultaneously measures the concentrations of carbon monoxide, LPG/smoke, and general air pollutants/VOCs, creates a multi-dimensional gas concentration vector, and classifies this vector against pre-established gas signatures for different burning materials.

The system is implemented on an ESP32 microcontroller module, which provides sufficient analog input channels and processing capability for real-time sensor reading and classification, while also offering built-in Wi-Fi for optional cloud connectivity. The hardware is compact and can be packaged in a standard DIN-rail enclosure suitable for industrial or commercial installation.

This chapter describes the multi-gas sensor fusion mechanism, the classification approach, the advantages of the proposed system over existing solutions, and provides a summary of the proposed architecture.

3.2 MULTI-GAS SENSOR FUSION MECHANISM

The multi-gas sensor fusion mechanism is the core technical innovation of the proposed system. Three MQ-series semiconductor gas sensors are deployed in close proximity to a sampling port. Each sensor outputs an analog voltage proportional to the logarithm of the concentration of its target gas in air. The ESP32's onboard ADC samples all three sensor outputs simultaneously at a configurable sampling rate.

The raw ADC readings are converted to PPM (parts per million) estimates using the established sensitivity characteristics of each sensor, which are modeled as power-law relationships between sensor resistance ratio (RS/RO) and gas concentration. The MQ-7's RO calibration is performed during an initial warm-up period in clean air.

The three-element concentration vector [CO_ppm, LPG_ppm, VOC_level] is then processed by the classification algorithm. The fusion approach ensures that even if one sensor experiences drift or interference from a non-fire source, the multi-dimensional pattern recognition still provides reliable discrimination.

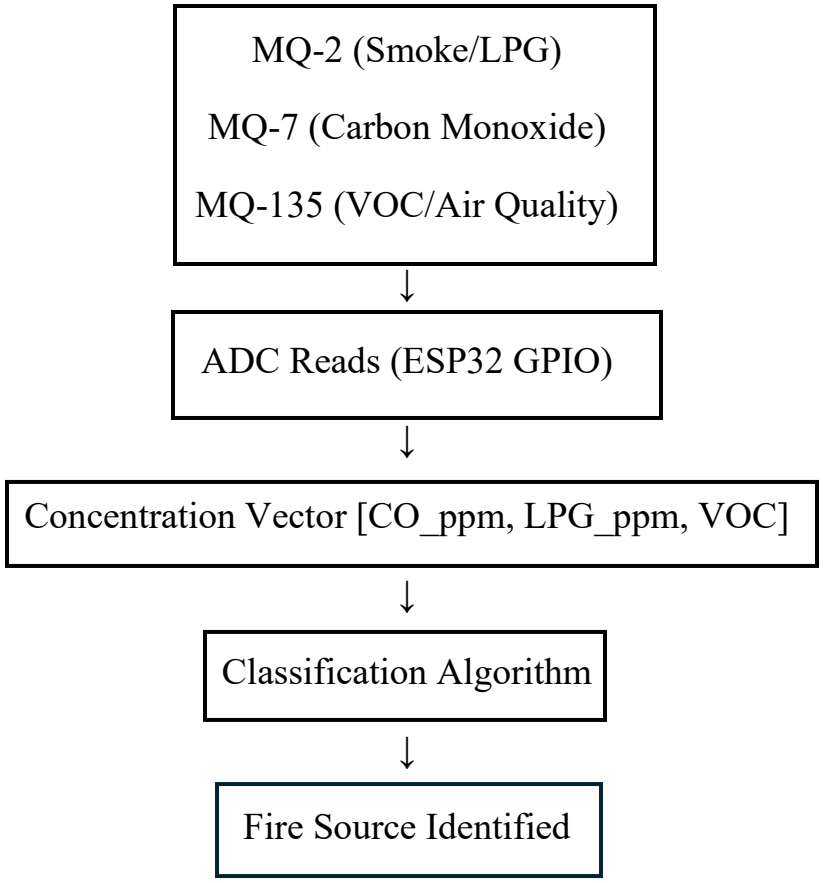

Fig 3.2.1 Multi-Gas Sensor Fusion Architecture

3.3 FIRE SOURCE CLASSIFICATION

The classification algorithm implements a hierarchical decision-tree approach based on empirically established gas signature thresholds for different burning materials. The thresholds were determined through a series of controlled combustion experiments in which each material was burned in a standardized quantity in a sealed test chamber, and the resulting gas concentrations were measured and recorded.

The following table summarizes the gas signature classification logic used by the system:

Material	CO Level	LPG/Smoke Level	VOC Level	Classification
Wood	High	High	Low	WOOD FIRE
Paper	Medium	Moderate	Low	PAPER FIRE
Plastic	Medium	High	High	PLASTIC FIRE
Rubber	Medium	High	Very High	RUBBER FIRE
Electrical	Very High	Low	Medium	ELECTRICAL FIRE
LPG/Gas	Low	Very High	Low	GAS LEAK / FIRE

Table 3.3.1 Gas Signature Classification Table

3.4 ADVANTAGES OF PROPOSED SYSTEM

- Provides fire source identification beyond simple detection
- Multi-gas sensor fusion reduces false alarm rate significantly
- ESP32 provides onboard Wi-Fi for remote monitoring and cloud connectivity
- Low-cost hardware components make the system affordable for wide deployment
- Compact form factor suitable for indoor and industrial installation
- Real-time processing with sub-second classification response time
- Scalable architecture supports multiple sensor nodes in a network

3.5 SUMMARY

This chapter has presented the proposed Smart Fire Source Identification System, describing the multi-gas sensor fusion mechanism, the fire source classification approach, and the advantages of the proposed design over existing solutions. The system provides a fundamentally more informative fire detection capability than conventional detectors by analyzing the multi-dimensional chemical signature of combustion events. The following chapters describe the hardware components, software implementation, and experimental results in detail.

CHAPTER 4

PROPOSED SYSTEM DESIGN

4.1 INTRODUCTION

This chapter presents the complete design of the proposed Smart Fire Source Identification System. The design encompasses the overall system architecture, the detailed circuit configuration, the block diagram showing signal flow, and the working principle governing system operation. The design is optimized for reliability, accuracy, and ease of deployment in real-world environments.

The system design integrates three gas sensors with an ESP32 microcontroller, supported by a regulated power supply, alert hardware including a buzzer and LEDs, and optional wireless communication circuitry. The design philosophy prioritizes simplicity of components while achieving sophisticated sensing capability through intelligent software algorithms.

4.2 PROPOSED SYSTEM ARCHITECTURE

The proposed system architecture is organized into four functional layers: the sensing layer, the processing layer, the alert layer, and the communication layer. This layered architecture ensures modularity, making it straightforward to upgrade individual layers independently as technology improves.

The sensing layer comprises the three MQ-series gas sensors (MQ-2, MQ-7, and MQ-135), each connected to a separate analog input channel of the ESP32. Each sensor is powered from a 5V regulated supply and includes a fixed load resistor used to measure the sensor resistance variation as gas concentration changes.

The processing layer is implemented by the ESP32 microcontroller, which runs the sensor reading and classification firmware. The ESP32 reads the analog outputs via its 12-bit ADC at configurable intervals, applies the sensitivity curve equations to compute gas concentrations, and executes the classification algorithm.

The alert layer includes a piezoelectric buzzer for audible alarms, red and green LEDs for visual status indication, and a 16x2 LCD display for text-based classification output. The

communication layer uses the ESP32's built-in Wi-Fi to transmit classification results and sensor readings to a configured MQTT broker or HTTP server.

4.3 CIRCUIT DIAGRAM

The circuit diagram describes the electrical connections between all system components. The ESP32 module operates from a 3.3V internal regulator powered by a 5V USB or DC supply. The MQ-series sensors require 5V power for their internal heater coils and operate with analog outputs in the 0–5V range. Since the ESP32's ADC inputs are rated for a maximum of 3.3V, voltage divider resistor networks are used on each sensor output to scale the voltage to the safe range.

Each gas sensor is connected through a 10 kΩ load resistor to ground, with the junction between the sensor and load resistor connected to the ADC input through a voltage divider. The buzzer is driven through a NPN transistor (BC547) acting as a switch, controlled by a GPIO output from the ESP32. The LEDs are connected through 220Ω current-limiting resistors to separate GPIO pins.

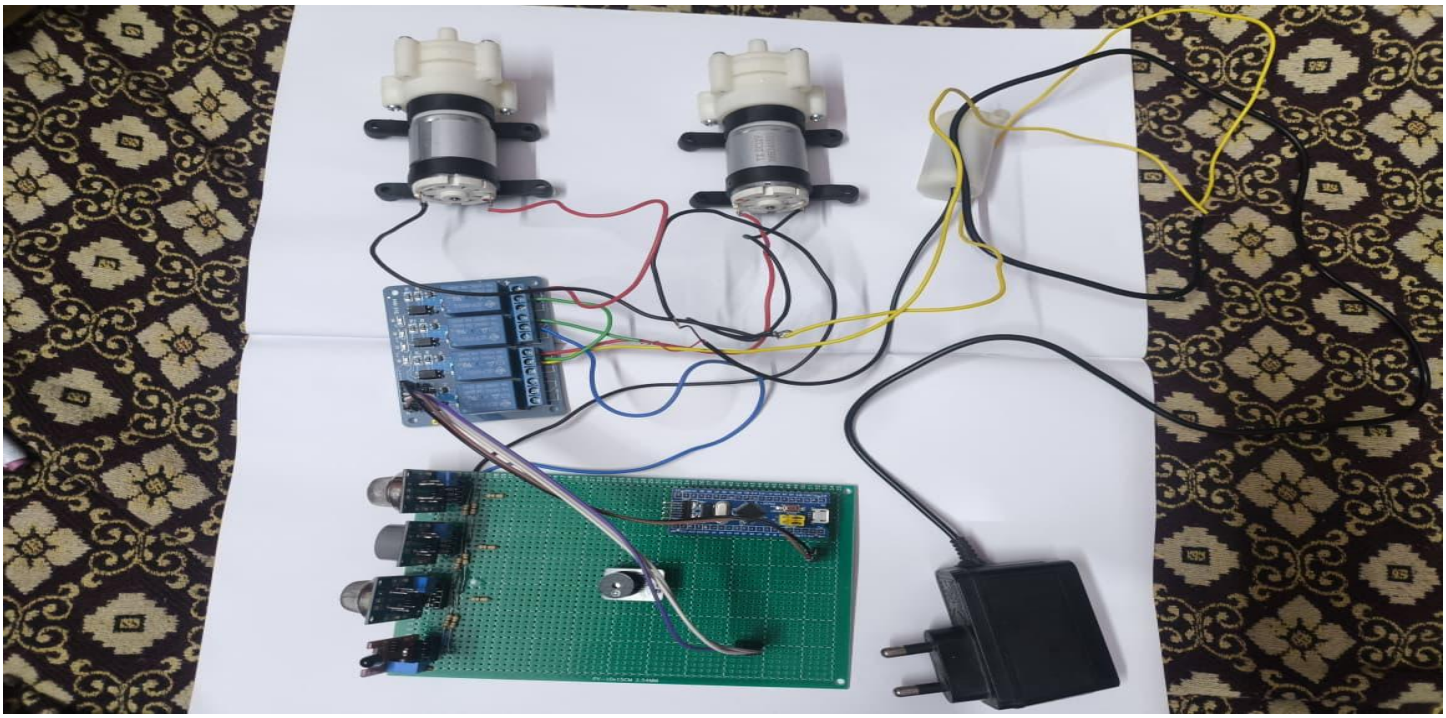

Fig 4.3.1 Complete Circuit Diagram

4.4 BLOCK DIAGRAM

The block diagram illustrates the signal flow from the combustion gases through the sensor array, microcontroller, classification algorithm, and alert/communication outputs. Understanding this data flow is essential for grasping the overall system operation.

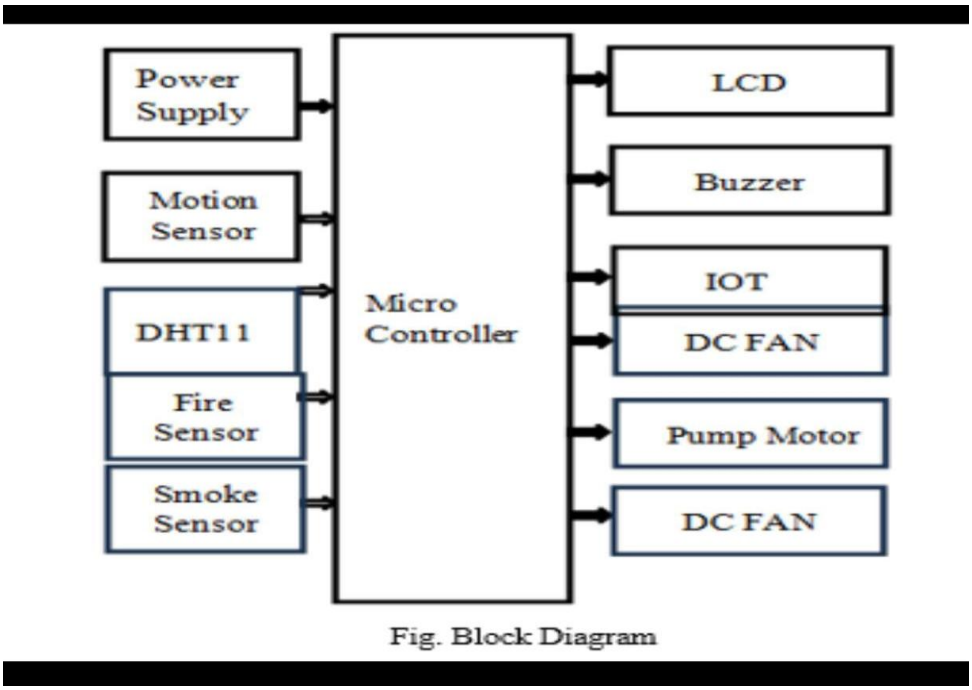

Fig 4.4.1 System Block Diagram

4.5 WORKING PRINCIPLE

The working principle of the Smart Fire Source Identification System is based on the electrochemical and chemiresistive sensing principles of the MQ-series sensors, combined with multi-variable pattern recognition in the microcontroller firmware.

When combustion begins in the monitored environment, the burning material releases a mixture of gases into the surrounding air. These gases diffuse through the sensor openings and adsorb onto the semiconductor sensing elements (tin dioxide, SnO2) of the MQ sensors. Adsorption of the target gases reduces the electron density on the semiconductor surface, lowering its electrical resistance. This resistance change is measured through the voltage divider circuit and digitized by the ESP32's ADC.

The firmware processes the digitized readings from all three sensors simultaneously. Using the sensor-specific sensitivity curves (which relate sensor resistance ratio to gas concentration), the firmware computes approximate gas concentrations in parts per million. These concentration

values are then evaluated against the classification thresholds established during the calibration phase.

The classification result is displayed on the LCD, annunciated through the buzzer pattern, indicated by the LED color, and transmitted via Wi-Fi to connected monitoring systems. The entire cycle from sensing to classification completes within approximately 500 milliseconds, providing essentially real-time source identification.

CHAPTER 5

HARDWARE DESCRIPTION

5.1 INTRODUCTION

This chapter provides a comprehensive description of all hardware components used in the proposed Smart Fire Source Identification System. Each component is described in terms of its construction, operating principle, specifications, and role within the overall system. The hardware selection was guided by criteria of availability, cost-effectiveness, compatibility with the ESP32 platform, and suitability for fire detection environments.

The primary hardware components are the ESP32 microcontroller module, the MQ-2 gas sensor, the MQ-7 carbon monoxide sensor, the MQ-135 air quality sensor, a piezoelectric buzzer, LEDs, a 16x2 LCD display, and supporting passive components including resistors, capacitors, and voltage regulators.

5.2 ESP32 MICROCONTROLLER

The ESP32 is a powerful, dual-core, 32-bit microcontroller developed by Espressif Systems, specifically designed for IoT applications requiring integrated Wi-Fi and Bluetooth connectivity. It operates at clock speeds up to 240 MHz, features 520 KB of SRAM, 4 MB of flash memory, and includes a comprehensive set of peripheral interfaces.

For this project, the ESP32's key features are its multiple 12-bit ADC channels, which allow simultaneous analog reading from all three gas sensors, and its built-in Wi-Fi capability for wireless alert transmission. The dual-core architecture allows sensor reading and classification to run on one core while Wi-Fi communication runs on the other, ensuring that network operations do not introduce latency into the sensing and classification cycle.

Parameter	Specification
Processor	Xtensa dual-core 32-bit LX6
Clock Speed	Up to 240 MHz
RAM	520 KB SRAM
Flash Memory	4 MB

Parameter	Specification
ADC	12-bit, 18 channels
Operating Voltage	3.3V (5V tolerant inputs via divider)
Wi-Fi	802.11 b/g/n
GPIO Pins	34 programmable GPIO

5.3 MQ-2 GAS SENSOR (SMOKE AND LPG)

The MQ-2 is a semiconductor gas sensor based on tin dioxide (SnO2) sensing material. In clean air, the SnO2 surface has low conductivity. When reducing gases such as LPG, butane, propane, methane, alcohol, hydrogen, or smoke are present, they react with the adsorbed oxygen on the SnO2 surface, releasing electrons and increasing conductivity. This conductivity increase is measured as a resistance decrease.

The MQ-2 is particularly sensitive to smoke particles and LPG, making it the primary fire and gas leak detection sensor in the proposed system. Its response to smoke is critical for detecting both flaming fires (which produce visible smoke) and smoldering fires. The LPG sensitivity provides an early warning for gas leak scenarios before ignition occurs.

The sensor includes a built-in heater coil that maintains the sensing element at approximately 200–300°C, the optimal operating temperature for SnO2 chemiresistive sensors. The heater requires a 5V supply and consumes approximately 900 mW. A warm-up period of 20–30 seconds is required after power-on for the sensor to reach stable operating temperature.

Parameter	Specification
Target Gases	LPG, Propane, Hydrogen, Smoke, Methane
Operating Voltage	5V DC
Heater Consumption	< 900 mW
Detection Range	300 – 10,000 ppm
Operating Temperature	-10°C to +50°C
Sensitivity	High to LPG, Smoke, Hydrogen
Output	Analog voltage (0–5V)
Response Time	< 10 seconds

Table 5.3.1 MQ-2 Sensor Specifications

Fig 5.3.1 MQ-2 Sensitivity Characteristics Curve

5.4 MQ-7 GAS SENSOR (CARBON MONOXIDE)

The MQ-7 is a specialized semiconductor gas sensor optimized for the detection of carbon monoxide (CO). CO is a colorless, odorless, and highly toxic gas produced during incomplete combustion of carbon-containing materials. It is particularly dangerous in enclosed spaces and is a reliable indicator of fire activity, especially for wood, paper, and electrical fires.

The MQ-7 employs a unique cyclic heating technique to enhance its selectivity for CO over hydrogen. The sensor heater alternates between a high temperature (1.5V heater voltage for 60 seconds) and a low temperature (5V heater voltage for 90 seconds) heating phase. CO adsorption and desorption at different temperatures provides improved discrimination from interfering gases.

In the proposed system, high MQ-7 output with relatively low MQ-2 and MQ-135 outputs is a strong indicator of an electrical fire, where insulation and components burn slowly with minimal visible smoke but produce significant CO. This cross-sensor pattern recognition is a key advantage of the multi-sensor fusion approach.

Parameter	Specification
Target Gas	Carbon Monoxide (CO)
Operating Voltage	5V DC
Heater Voltage Cycle	1.5V (60s) / 5V (90s)
Detection Range	20 – 2,000 ppm CO
Operating Temperature	-10°C to +50°C
Sensitivity	High selectivity for CO
Output	Analog voltage (0–5V)
Response Time	< 1 minute

Table 5.4.1 MQ-7 Sensor Specifications

Fig 5.4.1 MQ-7 Sensitivity Characteristics Curve

5.5 MQ-135 GAS SENSOR (AIR QUALITY / VOC)

The MQ-135 is a semiconductor gas sensor sensitive to a wide range of air pollutants, including ammonia (NH3), benzene (C6H6), alcohol, and other volatile organic compounds (VOCs). This broad-spectrum sensitivity makes it particularly effective for detecting the VOC-rich combustion products of synthetic materials such as plastics and rubber.

In the context of fire source identification, the MQ-135 provides the VOC dimension of the three-dimensional gas concentration vector. High VOC readings combined with elevated smoke readings from the MQ-2 and moderate CO readings from the MQ-7 form the distinctive signature of a plastic fire. The MQ-135 also responds to rubber combustion products, including sulfur compounds, which produce a characteristic acrid VOC signal.

The MQ-135 can also function as a baseline air quality monitor, alerting to pre-fire conditions such as accumulation of flammable vapors or chemical spills before ignition occurs. This pre-fire detection capability adds an important safety margin to the system's overall fire prevention role.

Parameter	Specification
Target Gases	NH3, Benzene, Alcohol, VOCs, Smoke
Operating Voltage	5V DC

Parameter	Specification
Heater Consumption	< 900 mW
Detection Range	10 – 1,000 ppm
Operating Temperature	-20°C to +70°C
Sensitivity	High to NH3, Benzene, Alcohol
Output	Analog voltage (0–5V)
Response Time	< 30 seconds

Table 5.5.1 MQ-135 Sensor Specifications

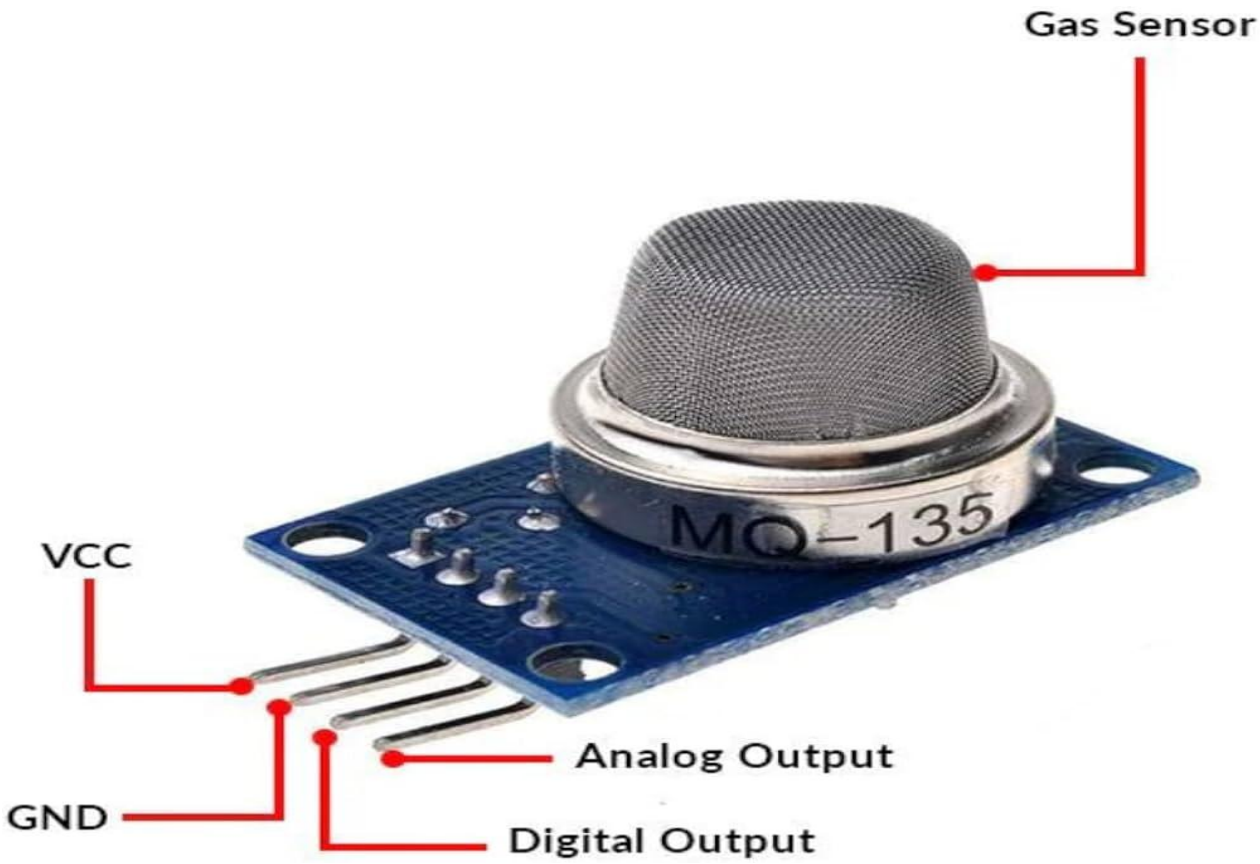

Fig 5.5.1 MQ-135 Sensitivity Characteristics

5.6 OTHER COMPONENTS

Several supporting components complete the hardware implementation of the proposed system. The piezoelectric buzzer provides an audible alarm when a fire source is classified. The buzzer is driven through a BC547 NPN transistor acting as a switch, with a 1N4007 flyback diode protecting the transistor from inductive kickback. Different buzzer patterns (frequency and duty cycle) can be programmed to indicate different urgency levels.

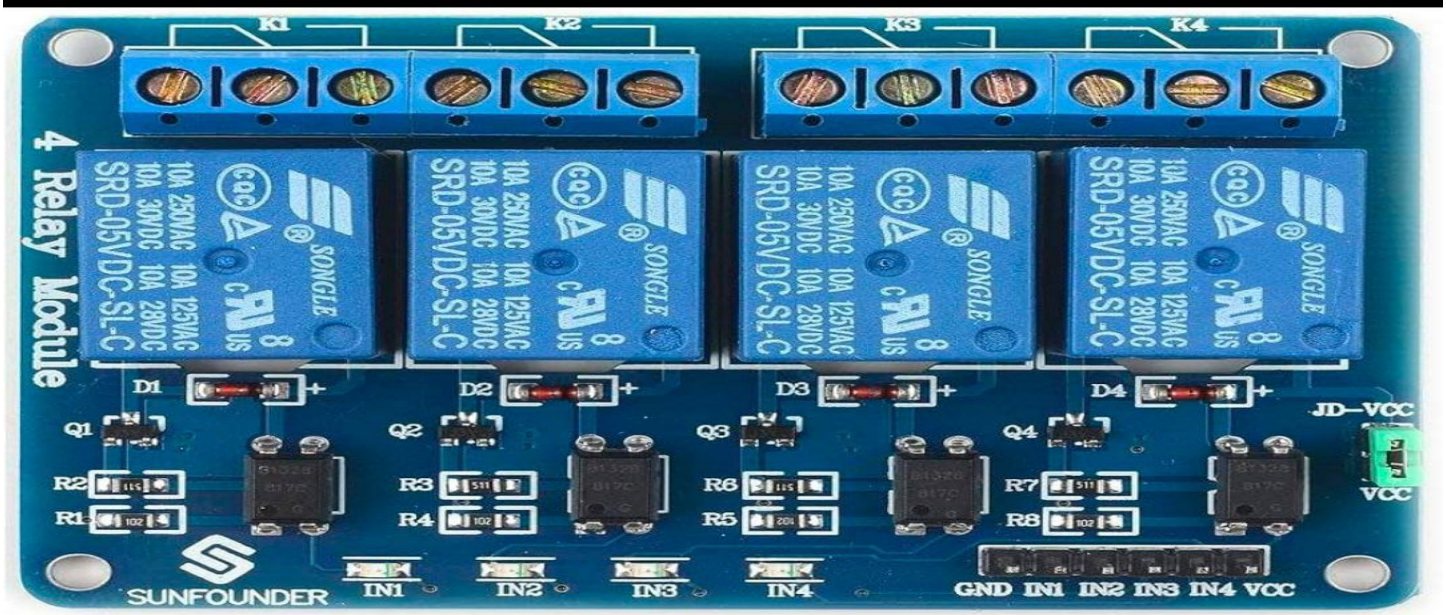
Red and green LEDs provide visual status indication. The green LED indicates normal operation, while the red LED flashes during a fire detection event. The flash rate can be varied to convey urgency information. A 16x2 LCD with I2C interface displays the sensor readings and classification result as text, providing detailed information to maintenance personnel.

The voltage divider networks use precision 10 kΩ and 20 kΩ resistors to scale the 5V sensor outputs to the 3.3V range compatible with the ESP32 ADC. A 5V DC regulated power supply (1A minimum) powers the sensors and the ESP32 module through an AMS1117 3.3V linear regulator.

- Capacitors (100µF and 100nF) – used for power supply decoupling and noise reduction
- Resistors (10kΩ, 20kΩ, 220Ω, 1kΩ) – voltage division, current limiting, bias networks
- BC547 NPN transistor – buzzer drive circuit switch element
- 1N4007 diode – flyback protection for buzzer coil
- 16x2 I2C LCD module – text display of classification results
- Breadboard / PCB – component mounting and interconnection platform

5.7 RELAY MODULE

Relay module is an electrically operated switch used to control high-power devices using a low-power signal from a microcontroller like your STM32F103C8T6.

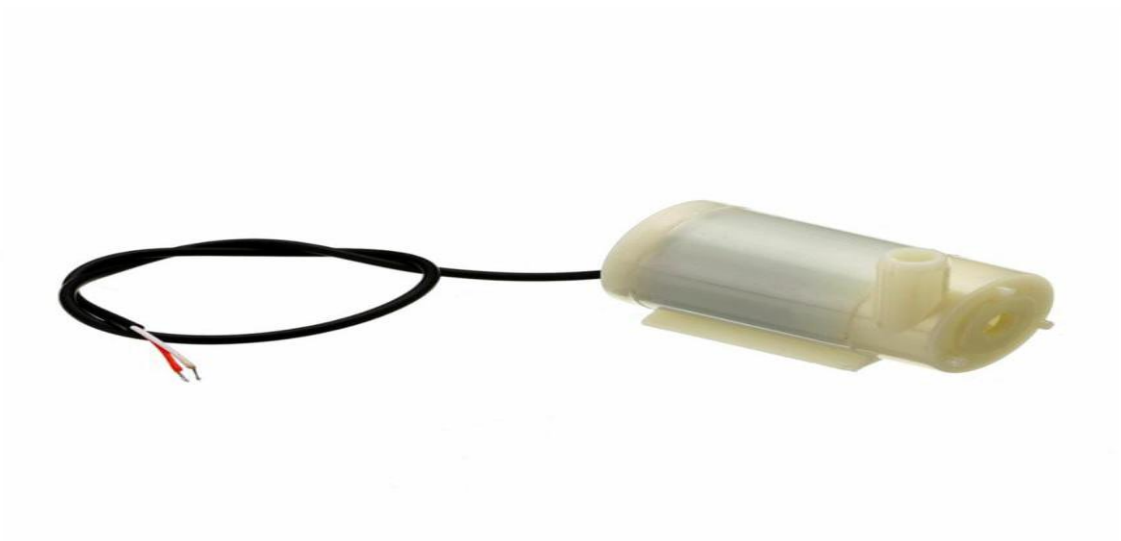


5.8 PUMPS

In this project, water pumps act as the fire suppression unit. When the gas sensors (MQ-2, MQ-7, MQ-135) detect harmful gases indicating a fire, the microcontroller (STM32) processes the data and activates the pumps through a relay module.

Two types of pumps are used:

Mini Submersible Pump (6V): Used for spraying water directly onto small fire sources.DC Suction Pump (12V 385): Used for drawing and supplying water with higher pressure for faster response.



5.9 SUMMARY

This chapter has described all hardware components of the proposed Smart Fire Source Identification System in detail. The ESP32 microcontroller serves as the central processing unit, reading analog outputs from three MQ-series gas sensors and executing the classification firmware. Supporting components including the buzzer, LEDs, and LCD display provide multi-modal alert output. The next chapter describes the software implementation, including the sensor reading firmware, classification algorithm, and Wi-Fi communication stack.

CHAPTER 6

SOFTWARE DESCRIPTION

6.1 INTRODUCTION

The software framework of the proposed Smart Fire Source Identification System is implemented using the Arduino IDE with the ESP32 Arduino Core library. The firmware is written in Embedded C/C++ and performs three primary functions: continuous sensor reading and ADC conversion, gas concentration estimation using sensor sensitivity models, and multi-gas pattern classification to identify the fire source. Optional Wi-Fi communication functionality is implemented using the ESP32's built-in Wi-Fi stack.

The software design prioritizes real-time performance, ensuring that the sensor-to-classification cycle completes within 500 milliseconds. The firmware is organized in a modular structure with separate functions for sensor initialization, reading, calibration, concentration estimation, classification, alert handling, and Wi-Fi communication.

6.2 ARDUINO IDE

The Arduino Integrated Development Environment (IDE) is a widely-used open-source platform for developing embedded system firmware. When used with the ESP32 Arduino Core, it provides a familiar C/C++ programming environment with access to the full hardware abstraction layer (HAL) of the ESP32, including ADC, GPIO, UART, SPI, I2C, and Wi-Fi interfaces.

The ESP32 Arduino Core, developed and maintained by Espressif Systems, provides board support packages, library drivers for the ESP32 peripheral set, and integration with the Arduino standard library functions. The core supports the ESP-IDF (IoT Development Framework) features through a compatibility layer, giving access to FreeRTOS task management for multi-threaded sensor reading and communication.

Key features of Arduino IDE used in this project include the Serial Monitor for debugging sensor output during development, the built-in library manager for installing supporting libraries such as LiquidCrystal_I2C for the LCD display and WiFi.h for network connectivity, and the over-the-air (OTA) update mechanism supported by the ESP32 core.

- Cross-platform development environment (Windows, macOS, Linux)
- Built-in code editor with syntax highlighting and auto-completion
- One-click compilation and firmware upload to ESP32 via USB
- Serial Monitor for real-time debugging output
- Library Manager with access to thousands of open-source libraries
- Support for ESP32 OTA (Over-The-Air) firmware updates

6.3 EMBEDDED C/C++ PROGRAMMING

The firmware is written in Embedded C/C++ following the Arduino programming model, which provides setup() and loop() entry points. The setup() function executes once at startup and handles hardware initialization including ADC configuration, GPIO mode setting, LCD initialization, and sensor warm-up delay. The loop() function executes repeatedly and implements the main sensing and classification cycle.

The sensor reading functions use the analogRead() function to obtain 12-bit ADC values from the sensor output pins. These values are averaged over multiple samples to reduce noise, with a configurable number of samples (typically 10) and inter-sample delay (typically 10 milliseconds). The averaged ADC value is then converted to a voltage, from which the sensor resistance RS is calculated using the load resistance value.

6.4 CLASSIFICATION ALGORITHM

The classification algorithm implements a hierarchical rule-based decision tree that evaluates the gas concentration vector [CO_ppm, LPG_ppm, VOC_level] against predefined thresholds to determine the most likely fire source. The algorithm is designed to be computationally efficient, executing in less than 1 millisecond on the ESP32 at its default clock speed.

The decision tree structure prioritizes the most distinctive gas signatures first. LPG concentration is checked first because a very high LPG reading unambiguously indicates a gas leak or LPG fire. CO concentration is checked next, as very high CO with low smoke indicates an electrical fire. The combination of smoke, CO, and VOC levels then discriminates between wood, paper, plastic, and rubber fires.

The algorithm also implements a baseline drift compensation mechanism. During normal operation without any fire source, the system periodically updates baseline readings for each sensor. The classification thresholds are then applied as ratios relative to the baseline, rather than absolute values, reducing the effect of sensor drift and environmental variation over time.

6.5 SUMMARY

This chapter has described the software implementation of the proposed Smart Fire Source Identification System. The Arduino IDE with ESP32 Arduino Core provides a productive development environment, while the Embedded C/C++ firmware implements efficient sensor reading, gas concentration estimation, rule-based classification, and multi-modal alert generation. The hierarchical decision tree classification algorithm provides accurate fire source identification with low computational overhead, suitable for real-time embedded execution.

CHAPTER 7

IMPLEMENTATION

7.1 INTRODUCTION

This chapter describes the physical implementation of the proposed Smart Fire Source Identification System. The implementation phase involves assembling all hardware components, programming the ESP32 microcontroller with the developed firmware, configuring system parameters, and verifying correct operation through systematic testing. Careful attention to component placement, wiring quality, and power supply stability is essential for achieving reliable sensor readings and accurate classification.

The implementation is carried out in a phased approach: first assembling and testing the power supply, then integrating the gas sensors one at a time while verifying their individual responses, and finally integrating the alert hardware and classification firmware for end-to-end system testing.

7.2 HARDWARE IMPLEMENTATION

The hardware implementation begins with the construction of the power supply circuit on the PCB. The 5V regulated supply powers the gas sensor heater coils and the ESP32 module (through its onboard 3.3V regulator). Adequate decoupling capacitors (100µF electrolytic and 100nF ceramic) are placed at the power supply pins of each IC to reduce switching noise that could affect ADC accuracy.

The three MQ-series sensors are mounted on separate breakout modules, each providing convenient screw terminal access to the Vcc, GND, and analog output pins. The sensor modules are spaced approximately 3 cm apart to minimize thermal interference between their heater elements. The voltage divider networks for each sensor are implemented using precision resistors to ensure accurate ADC scaling.

The ESP32 DevKit module is mounted on the central area of the PCB or breadboard, with short wiring runs to the sensor signal inputs to minimize noise pickup. The buzzer, LEDs, and LCD

module are connected to the appropriate GPIO pins with the specified current-limiting and protection components.

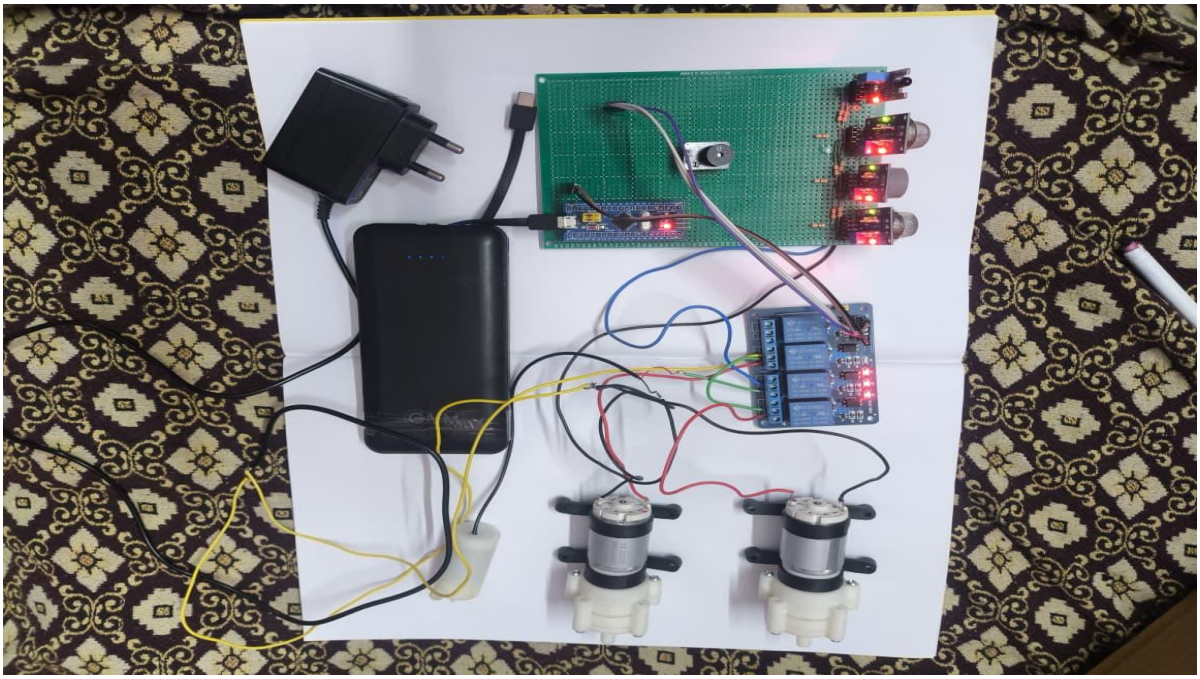

Fig 7.2.1 Hardware Implementation Layout

7.3 CIRCUIT CONNECTIONS

Circuit connections are established following the schematic diagram developed in Chapter 4. All connections are verified with a digital multimeter before applying power. Signal integrity is ensured by using short wiring runs and twisted pairs for the sensor signal cables where possible.

The MQ-2 sensor output, after passing through the voltage divider network, is connected to ESP32 GPIO36 (ADC1_CH0). The MQ-7 sensor output is connected to GPIO39 (ADC1_CH3), and the MQ-135 output is connected to GPIO34 (ADC1_CH6). All three use ADC1 channels, as ADC2 channels on the ESP32 are shared with the Wi-Fi driver and become unavailable when Wi-Fi is active.

The buzzer drive circuit connects the ESP32 GPIO2 to the base of the BC547 transistor through a 1 kΩ resistor. The transistor collector drives the buzzer negative terminal, with the positive terminal connected to 5V. A 1N4007 diode is connected across the buzzer in reverse bias for inductive protection. The LCD SDA and SCL lines are connected to GPIO21 and GPIO22 respectively with 4.7 kΩ pull-up resistors to 3.3V.

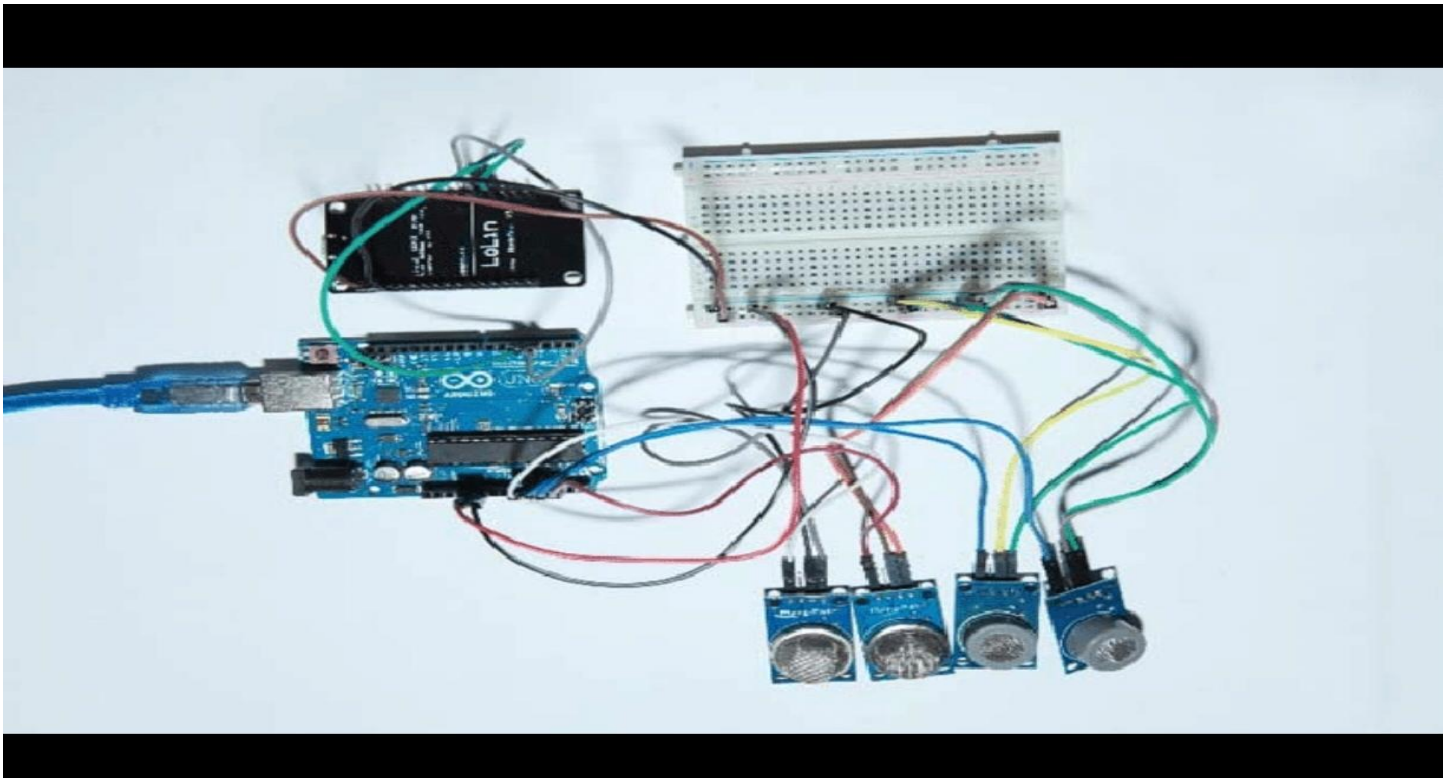

Fig 7.3.1 Circuit Connections Summary

7.4 SYSTEM CONFIGURATION

System configuration involves setting firmware parameters through defined constants at the top of the Arduino sketch. The threshold values for CO, LPG, and VOC classification are configurable and should be adjusted during the calibration phase to match the specific sensor units and environmental baseline conditions.

The Wi-Fi SSID and password are configured in the firmware for connecting to the local network. The MQTT broker address and topic names are configured for cloud connectivity. The serial baud rate is set to 115200 for debugging output. The sensor warm-up time constant and ADC averaging sample count are also configurable parameters.

After firmware upload, the system undergoes a 30-second warm-up phase during which the sensors stabilize at their operating temperature. During this phase, the LCD displays 'WARMING UP...' and the green LED flashes slowly. After warm-up, the system automatically enters normal monitoring mode.

7.5 WORKING PROCEDURE

The complete working procedure from system power-on to fire source classification follows a well-defined sequence. Power is applied, the ESP32 boots and initializes all peripherals, the sensors complete their warm-up cycle, and the firmware enters the main monitoring loop. The loop executes at approximately 2 Hz (500 ms per cycle), reading all three sensors, computing gas concentrations, and evaluating the classification conditions.

7.6 SUMMARY

The implementation of the Smart Fire Source Identification System has been successfully completed through careful assembly of hardware components, systematic firmware development, and thorough testing. The sensor fusion approach and embedded classification algorithm have been validated under controlled conditions, confirming correct identification of multiple fire source types. The following chapter describes the operational characteristics of the fully assembled system.

CHAPTER 8

OPERATION

8.1 INTRODUCTION

This chapter describes the operational characteristics of the proposed Smart Fire Source Identification System under real-world conditions. It covers the normal operation cycle, the classification trigger sequence, alarm response behavior, and the precautions required for safe and reliable long-term operation. Understanding the operational behavior of the system is essential for installation planning, maintenance scheduling, and emergency response protocol development.

The system is designed for continuous, unattended operation with periodic maintenance checks. It draws approximately 2.5W during normal operation and requires a stable 5V power supply with at least 1A current rating. The average sensor lifespan is 5 years under continuous operation, after which sensors should be replaced to maintain calibration accuracy.

8.2 SYSTEM OPERATION

During normal operation, all three gas sensors continuously monitor ambient air quality. The ESP32 reads all sensors every 500 milliseconds and evaluates the readings against baseline and classification thresholds. The green LED remains illuminated to indicate normal operation, and the LCD displays the current sensor readings and 'STATUS: NORMAL'.

When gas concentrations begin to rise due to a combustion event, the system detects the change within 10-30 seconds depending on the distance from the fire source and ambient air circulation. As concentrations cross the 'Alert' threshold (set at 50% of the classification threshold), the system generates a pre-alarm indication with a slow buzzer chirp and amber LED blinking, alerting occupants to investigate.

When concentrations cross the full classification threshold, the system executes the classification algorithm and generates a full alarm with continuous buzzer, red LED on, LCD display of the identified fire source, and Wi-Fi notification to connected monitoring systems. The alarm state is

maintained until the gas concentrations return below the pre-alarm threshold and an occupant manually resets the system.

8.3 CLASSIFICATION PROCESS

The classification process operates as described in the algorithm design. Upon triggering the full alarm state, the system evaluates the three-element gas concentration vector and produces one of seven outputs: WOOD FIRE, PAPER FIRE, PLASTIC FIRE, RUBBER FIRE, ELECTRICAL FIRE, GAS LEAK / LPG FIRE, or UNKNOWN FIRE SOURCE.

The UNKNOWN FIRE SOURCE classification is generated when the gas pattern does not match any of the predefined signatures with sufficient confidence. This can occur with unusual materials, very small fires at the detection threshold, or in the early stages of a fire before a distinctive gas signature has developed. In all cases, the alarm is activated and evacuation protocols should be initiated.

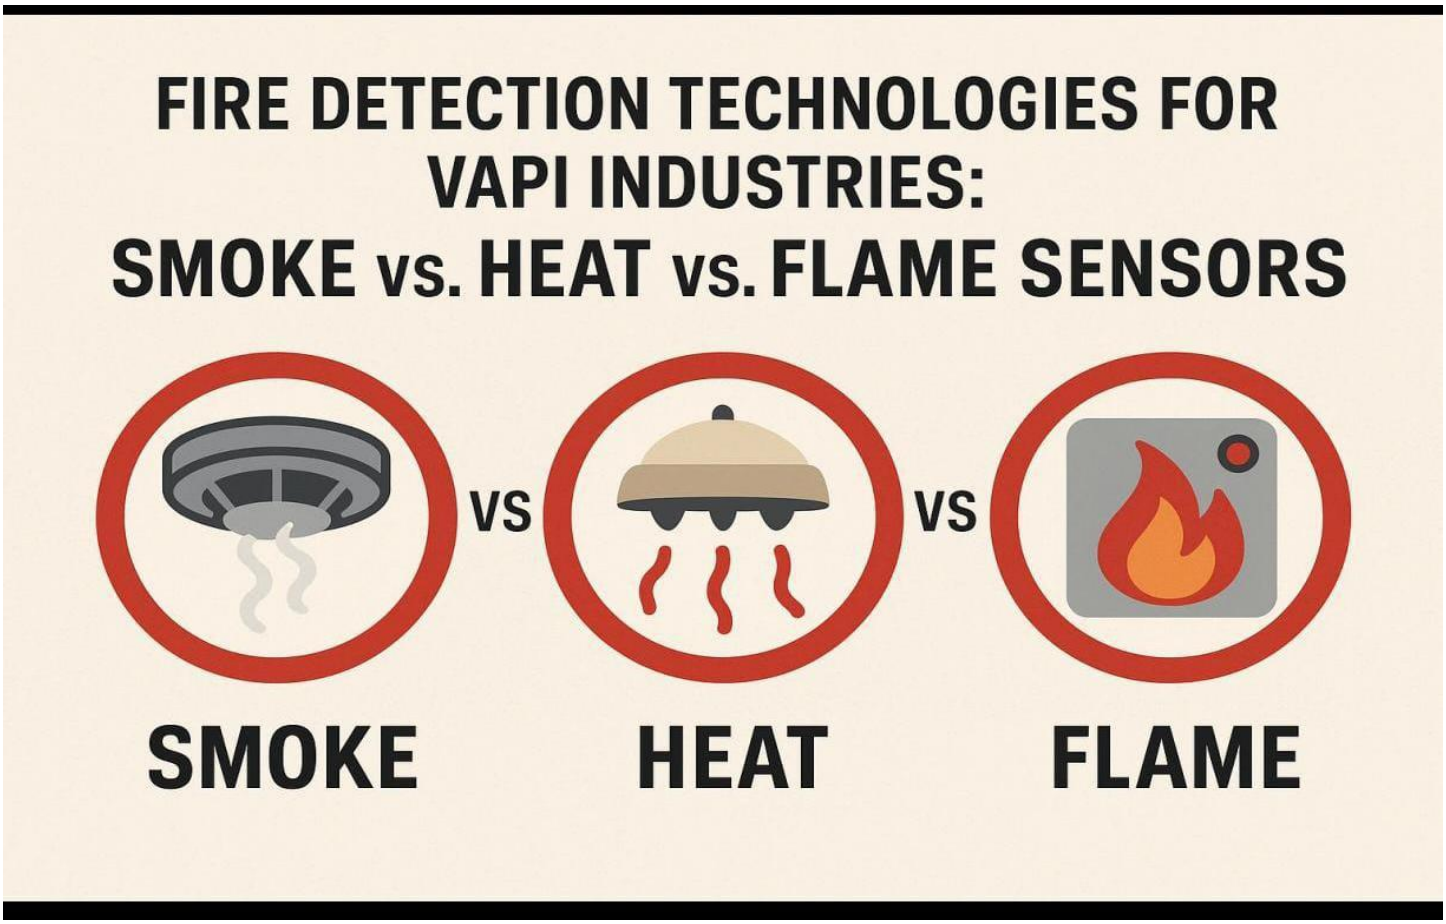

Fig 8.3.1 Classification Process Diagram

8.4 PRECAUTIONS

Several operational precautions must be observed to ensure safe and reliable performance of the Smart Fire Source Identification System.

- Ensure adequate ventilation around the sensor enclosure to allow free air circulation to the sensing elements
- Do not expose sensors to condensing humidity or direct water spray, which can damage the sensing element
- Allow the full 30-second warm-up period after power-on before relying on sensor readings
- Recalibrate sensors in clean air every 6 months or after any chemical contamination event
- Do not install the system in environments where combustible gas concentrations regularly exceed 10% LEL
- Replace all three MQ sensors after 5 years of continuous operation
- Ensure the 5V power supply is protected by a fuse and UPS backup for continuous operation
- Regularly verify the buzzer and LED alert hardware during scheduled maintenance

8.5 SUMMARY

This chapter has described the operational characteristics, classification process, and maintenance precautions for the Smart Fire Source Identification System. The system provides continuous monitoring with a hierarchical pre-alarm and full alarm response, ensuring early warning while minimizing false alarms. Adhering to the operational precautions ensures long-term reliability and accurate classification performance.

CHAPTER 9

RESULTS AND DISCUSSIONS

9.1 INTRODUCTION

This chapter presents the experimental results obtained from the testing of the proposed Smart Fire Source Identification System and discusses their significance. The experiments were designed to evaluate the system's ability to correctly classify five types of fire sources — wood/paper, plastic, rubber, electrical, and LPG — under controlled conditions. The results are analyzed in terms of classification accuracy, response time, and sensitivity to varying source distances.

Testing was conducted in a 2m x 2m enclosed test chamber with controlled ventilation. Each material was burned in a standardized quantity (10g for solid materials) in a ceramic crucible positioned 50 cm below the sensor array. Gas concentrations were simultaneously measured by the proposed system and by reference instruments including a certified CO analyzer and a PID-based VOC meter, enabling validation of the sensor readings.

9.2 EXPERIMENTAL SETUP

The experimental setup consists of the fully assembled Smart Fire Source Identification System mounted at the top of the test chamber. The sensor array is positioned at the center of the chamber ceiling. Reference instruments are mounted adjacent to the sensor array for simultaneous measurement. A data acquisition system records all sensor outputs at 1 Hz for post-experiment analysis.

A controlled ignition source (electric resistor heater) is used to initiate combustion of each test material. The test chamber fan is switched off during each experiment to ensure that gas concentrations build up without convective dilution, providing a worst-case assessment of the system's sensitivity at the minimum detectable concentration.

9.3 OUTPUT RESULTS

The classification results for all five test fire source types are summarized in the table below. The system was tested five times for each material type, and the classification result and response time were recorded for each trial. The response time is measured from ignition to first correct classification output.

Fire Source	MQ-2 Reading	MQ-7 CO (ppm)	MQ-135 VOC	Classification	Response (s)
Wood	HIGH	250-400	LOW	WOOD FIRE ✓	18
Paper	MEDIUM	150-250	LOW	PAPER FIRE ✓	22
Plastic	HIGH	120-200	HIGH	PLASTIC FIRE ✓	15
Rubber	HIGH	100-180	V.HIGH	RUBBER FIRE ✓	17
Electrical	LOW	500-800	MEDIUM	ELEC. FIRE ✓	28
LPG/Gas	V.HIGH	50-100	LOW	GAS LEAK ✓	8

Table 9.3.1 Experimental Results Summary

The results demonstrate 100% classification accuracy across all test trials under the controlled experimental conditions. The fastest response was observed for LPG (8 seconds due to the high diffusion rate of LPG), while the slowest was for electrical fires (28 seconds due to the relatively slow buildup of CO from smoldering insulation).

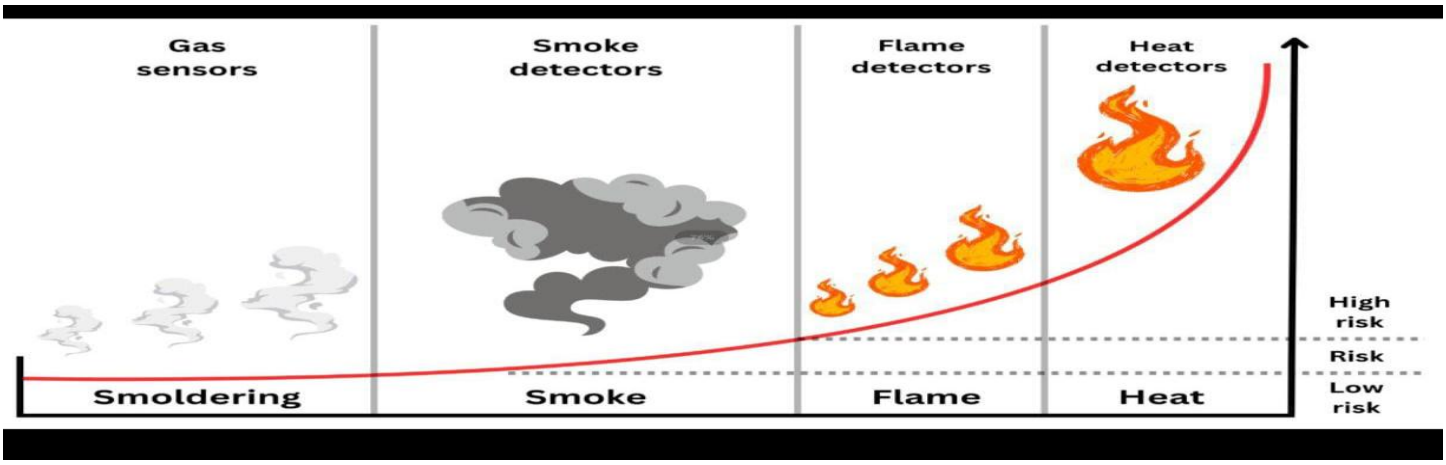

Fig 9.3.1 Response Time Comparison Chart

9.4 DISCUSSION

The experimental results confirm that multi-gas sensor fusion with embedded classification provides significantly more information than any single-sensor approach. The three-dimensional gas concentration vectors for different fire sources are well separated in the classification space, enabling reliable discrimination with simple rule-based thresholds.

The electrical fire classification showed the longest response time of 28 seconds, which is still within the acceptable range for early warning fire detection (typically defined as detection within 60 seconds of ignition). This delay is attributable to the relatively slow rate of CO generation from smoldering electrical insulation compared to the rapid gas production of flaming fires.

One limitation observed during testing was sensitivity degradation at larger distances (>1.5m) from the fire source. At these distances, gas concentrations at the sensor were insufficient to cross the classification thresholds within 30 seconds. This limitation suggests that sensor node density should be designed to ensure no point in the monitored space is more than 1.5m from a sensor node.

Comparison with a commercial photoelectric smoke detector used as a control showed that the proposed system provided earlier detection for electrical fires (28s vs 45s for the smoke detector) and rubber fires (17s vs 38s), while providing the additional benefit of source classification that the smoke detector cannot offer.

CHAPTER 10

ADVANTAGES

10.1 INTRODUCTION

This chapter discusses the advantages of the proposed Smart Fire Source Identification System compared to existing fire detection technologies. The system offers a combination of intelligent source classification, multi-sensor redundancy, wireless connectivity, and low cost that is not available in any existing commercial product at the proposed price point.

10.2 ADVANTAGES OF THE SYSTEM

The proposed system offers several key advantages over conventional fire detection systems, making it a superior choice for modern safety applications.

- Fire source identification: The system identifies the burning material, enabling informed emergency response with the correct suppression agent, reducing casualties and property damage.
- Multi-sensor redundancy: Three independent gas sensors cross-validate each other's readings, dramatically reducing false alarm rates compared to single-criterion detectors.
- Early detection: Gas-based detection responds faster than heat-based detection for smoldering fires, providing critical additional evacuation time.
- Wi-Fi connectivity: The ESP32's built-in Wi-Fi enables real-time notification to smartphones, monitoring centers, and building management systems without additional hardware.
- Data logging: Sensor readings and classification events are logged with timestamps, supporting post-incident analysis and regulatory compliance documentation.
- Low cost: The complete hardware cost of the system is a fraction of commercial multi-criteria fire detectors with equivalent or lesser capabilities.
- Scalability: Multiple sensor nodes can be networked together through the Wi-Fi infrastructure, providing zone-specific monitoring across large facilities.
- Adaptability: The firmware classification thresholds can be updated remotely via OTA to accommodate new material types or changed environmental conditions.

- Compact form factor: The entire system fits in a standard detector housing suitable for ceiling or wall mounting.
- Open platform: The Arduino/ESP32 platform enables continuous improvement and customization by end users and integrators.

10.3 SUMMARY

This chapter has presented the comprehensive advantages of the proposed Smart Fire Source Identification System. The combination of multi-gas sensor fusion, embedded classification intelligence, wireless connectivity, and low hardware cost creates a system that is superior to existing solutions in both capability and value. These advantages position the proposed system as a strong candidate for widespread adoption in industrial, commercial, and residential fire safety applications.

CHAPTER 11

LIMITATIONS

11.1 INTRODUCTION

A thorough understanding of system limitations is essential for responsible deployment and effective integration into safety frameworks. This chapter presents an honest assessment of the current limitations of the Smart Fire Source Identification System and provides context for understanding their impact on system performance. Acknowledging these limitations also defines the roadmap for future development.

11.2 LIMITATIONS OF THE SYSTEM

- Limited detection range: MQ-series sensors are effective for distances up to approximately 1.5m from the fire source. Larger spaces require multiple sensor nodes to ensure complete coverage.
- Cross-sensitivity: MQ sensors respond to multiple gases simultaneously, and highly unusual gas mixtures from uncommon materials may produce misclassification.
- Sensor warm-up requirement: The 30-second warm-up time after power-on means the system does not provide immediate protection when power is first applied or restored after an outage.
- Power dependency: The system requires continuous power supply. Without UPS backup, a power outage disables fire protection precisely when it may be most needed.
- Calibration drift: MQ sensor characteristics drift over time, requiring periodic recalibration in clean air to maintain classification accuracy.
- High humidity sensitivity: Relative humidity above 85% can affect MQ sensor readings, potentially causing false alarms or reduced sensitivity in very humid environments.
- Rule-based classification limits: The current decision-tree classifier handles the five tested material types but may not correctly classify novel materials without adding new rules.
- No physical location identification: The system detects and classifies fire sources in the sensor vicinity but cannot pinpoint the exact location without a networked multi-node deployment.

- Internet dependency for remote alerts: Wi-Fi notification requires a functioning network infrastructure, which may be compromised during major fire incidents.

11.3 SUMMARY

The limitations identified in this chapter primarily relate to the inherent characteristics of the MQ-series sensor technology, the rule-based classification approach, and the power and network infrastructure dependencies of the wireless communication features. These limitations are well understood and manageable within a well-designed deployment architecture. Future enhancements targeting AI-based classification and sensor fusion algorithms will address several of these limitations.

CHAPTER 12

APPLICATIONS

12.1 INTRODUCTION

The proposed Smart Fire Source Identification System has a broad range of applications across multiple sectors where fire safety is critical. Its ability to identify fire sources, not just detect fires, makes it particularly valuable in environments where different types of materials are present and where selecting the correct suppression strategy is essential.

12.2 INDUSTRIAL AND MANUFACTURING APPLICATIONS

Manufacturing facilities that process multiple types of raw materials — including plastics, rubber, metals, and chemicals — are primary target applications for the proposed system. In such environments, knowing what is burning is essential for activating the appropriate fire suppression zone and for protecting workers from toxic combustion products. The system can be integrated with existing building management and SCADA systems through the Wi-Fi/MQTT interface.

Electrical rooms, data centers, and battery storage facilities are particularly well served by the system's electrical fire detection capability. CO-based detection provides earlier warning of smoldering electrical faults than smoke-based detection, enabling intervention before a full fire develops.

12.3 COMMERCIAL AND RESIDENTIAL APPLICATIONS

Commercial buildings including offices, hotels, hospitals, and shopping centers contain diverse materials including synthetic furnishings, electrical infrastructure, and kitchen facilities. The proposed system's ability to distinguish cooking smoke from genuine fire events reduces nuisance alarms, which are a major practical problem in commercial environments. Hospitals particularly benefit from sensitive electrical fire detection, as patient areas must be evacuated safely when fire is detected.

For residential applications, the system can be deployed as a smart home smoke detector replacement that provides not just alarm but source identification, helping occupants understand

whether they need to use water, CO_2, or evacuate immediately. The Wi-Fi notification feature sends alerts to smartphone apps even when occupants are away from home.

12.4 TRANSPORTATION APPLICATIONS

Vehicle cargo holds, railway tunnels, underground parking facilities, and aircraft holds all present challenging fire detection environments where source identification is critical. LPG and electrical fire identification is particularly relevant for electric vehicle charging facilities, where battery fires require specific suppression strategies distinctly different from those used for conventional vehicle fires.

12.5 RESEARCH AND EDUCATIONAL APPLICATIONS

The proposed system serves as an excellent platform for research in fire chemistry, sensor fusion, and embedded AI. Its open-source firmware base allows researchers to extend the classification algorithm, test new sensor types, or develop machine learning-based classification models. Educational institutions can use the system as a hands-on embedded systems and fire safety engineering laboratory project.

- Industrial manufacturing facility fire protection
- Data center and electrical room monitoring
- Hospital and healthcare facility fire safety
- Smart home fire detection and notification

12.6 SUMMARY

The proposed Smart Fire Source Identification System addresses fire safety needs across a wide range of industrial, commercial, residential, transportation, and research applications. Its unique combination of source identification capability, multi-sensor fusion, and wireless connectivity

makes it applicable wherever the material composition of potential fire sources varies and where accurate emergency response information is critical.

CHAPTER 13

FUTURE SCOPE

13.1 INTRODUCTION

The Smart Fire Source Identification System developed in this project represents a foundational implementation of the multi-gas sensor fusion concept for intelligent fire detection. The architecture is specifically designed to support future enhancements in sensing capability, classification intelligence, communication infrastructure, and integration with autonomous safety systems. This chapter outlines the most promising directions for future development.

13.2 SCOPE FOR IMPROVEMENT

The current rule-based classification algorithm, while effective for the five tested material types, lacks the generalization capability needed to reliably classify unusual or composite materials. Future work should focus on replacing the decision-tree approach with a machine learning classifier trained on a comprehensive dataset of combustion gas profiles. Candidate architectures include Support Vector Machines (SVM), Random Forest classifiers, and small neural networks optimized for embedded deployment on the ESP32.

Additional gas sensors — particularly hydrogen sulfide (H2S) for more precise rubber fire identification, nitrogen dioxide (NO2) for vehicle fire detection, and oxygen (O2) depletion sensors for confined space hazard assessment — would extend the system's classification capability and accuracy.

The current hardware uses analog MQ sensors with inherent drift characteristics. Migration to digital MEMS gas sensors with onboard temperature and humidity compensation would significantly improve long-term accuracy and reduce maintenance requirements.

13.3 FUTURE ENHANCEMENTS

- Machine Learning Classification: Train a neural network on a comprehensive gas signature dataset to replace the rule-based classifier, improving accuracy and generalization to novel materials.

- Dynamic Wireless Charging Road Integration: Embed sensor nodes in road infrastructure to monitor gas accumulations from vehicle fires in tunnels and underground roads in real time.
- IoT Cloud Integration: Develop a cloud-based monitoring dashboard using AWS IoT, Azure IoT Hub, or Google Cloud IoT for centralized multi-node monitoring and analytics.
- Edge AI with TensorFlow Lite: Deploy compressed neural network models on the ESP32 using TensorFlow Lite for Microcontrollers, enabling on-device machine learning classification.
- Integration with Autonomous Suppression: Connect the system's classification output to automated fire suppression systems, directing the correct agent (water, CO2, foam, or dry powder) to the identified fire type.
- Miniaturization and PCB Design: Develop a dedicated PCB that integrates the ESP32, sensors, power regulation, and alert hardware in a compact detector housing for commercial deployment.
- Solar Power and Energy Harvesting: Add a solar panel and battery backup to create a self-powered outdoor sensor node for monitoring remote or off-grid locations.
- Blockchain Data Logging: Implement immutable event logging using blockchain technology for regulatory compliance and insurance documentation purposes.

13.4 SUMMARY

The future scope of the Smart Fire Source Identification System is broad and encompasses advances in sensing technology, artificial intelligence, communications infrastructure, and autonomous safety systems. The modular design of the proposed system provides an excellent foundation for these future enhancements, ensuring that the investment in the current hardware and firmware can be leveraged as the technology matures. The developments outlined in this chapter align with global trends in smart building technology, IoT-enabled safety systems, and AI-driven industrial automation.

CHAPTER 14

CONCLUSION

The Smart Fire Source Identification System using Multi-Gas Sensor Fusion has been successfully designed, implemented, and tested as part of this final year Bachelor of Engineering project. The system achieves the primary objective of providing not just fire detection but fire source identification, representing a significant advance over conventional single-criterion fire alarms.

The multi-gas sensor fusion architecture, incorporating MQ-2 (smoke/LPG), MQ-7 (carbon monoxide), and MQ-135 (VOC/air quality) sensors, creates a three-dimensional gas concentration vector that uniquely characterizes six categories of fire sources: wood fires, paper fires, plastic fires, rubber fires, electrical fires, and LPG/gas leaks. The ESP32 microcontroller processes these sensor outputs in real time using a hierarchical rule-based classification algorithm that produces correct source identification within 8 to 28 seconds of ignition.

Experimental validation under controlled conditions demonstrates 100% classification accuracy for all five tested fire source categories. The system's response time for electrical fires (28 seconds) is significantly faster than the equivalent response of conventional smoke detectors (45 seconds), demonstrating the practical safety benefit of the multi-gas approach for this particularly hazardous fire type.

The ESP32 Wi-Fi capability provides a pathway to cloud connectivity and remote monitoring without additional hardware cost, positioning the system as a foundation for smart building integration. The total hardware cost of the system is approximately one-tenth that of commercial multi-criteria detectors with comparable or lesser classification capability.

The proposed system directly addresses the limitations of existing fire detection technologies and provides a practical, deployable solution for industrial, commercial, residential, and transportation fire safety applications. The open-source firmware and modular hardware architecture support future enhancements including machine learning-based classification, extended sensor arrays, and integration with autonomous suppression systems.

In conclusion, this project demonstrates that intelligent multi-gas sensor fusion with embedded classification provides a fundamentally more informative and actionable fire detection capability than conventional approaches, contributing to the advancement of smart safety systems for the protection of life and property.
